L5 ANSWER 2 OF 2 CAPLUS COPYRIGHT 2006 ACS on STN  
 AB At least one bioactive agent is locally delivered to a location where a stent is implanted within a lumen in a patient's body. The bioactive agent includes DNA minor groove binder (such as CC-1065 or Duocarmycin); apocynin; RGD peptide (such as RGDFV); stilbene compound (such as resveratrol); camptothecin; des-aspartate angiotensin I; or ADF; or an analog or derivative thereof; or a combination or blend thereof with at least one other bioactive agent. The bioactive agent is generally locally delivered, such as by elution from the stent. The compds. and methods are of particular benefit for treating or preventing atherosclerosis, stenosis, restenosis, smooth muscle cell proliferation, occlusive disease, or other abnormal luminal cellular proliferation condition.

 L21 ANSWER 6 OF 6 PCTFULL COPYRIGHT 2006 Univentio on STN  
 ABEN The fusion polypeptides of this invention contain a variable region  
 sequence linked to an  
 effector sequence. The polypeptides do not form stable complexes in  
 solution, except in the presence  
 of an antigen.. . .  
  
 DETD  
 BACKGROUND  
 Antibody molecules have been designed by evolution to direct a  
 relatively non-specific  
 effector function on to a specific target. The antibody  
 repertory of an individual can be primed  
 against a limitless variety of foreign antigens. Upon revisititation of a  
 previously encountered antigen,  
 the induced antibody will bind and bring into play elements of  
 the complement cascade, or Fc  
 receptor bearing cells with all their capabilities.

The contemporary biomolecular chemist has capitalized on the targeting specificity of the

antibody for diagnostic and therapeutic purposes. Attaching the antibody with a label permits the detection or quantitation of antigen in a test solution. Attaching the antibody to a drug permits targeting to certain cells or tissues. New ways of delivering an effector function by way of an antibody are clearly of benefit.

Immunoassays used in routine clinical measurement involve an antibody specific for an analyte of interest in a biological sample. In separation based assays, the detecting of the complex involves a process wherein the complex formed is physically separated from either unreacted analyte, unreacted antibody, or both (U.S. Patent No. 3,646,346). The complex can be first formed in the fluid phase, and then subsequently captured by. . .

(U.S. Patent No. 4,708,929). Two subunits of the enzyme P-galactosidase associate to provide the detectable signal, which is quantitatively affected by analyte-specific antibody except in the presence of a sample containing free analyte.

Recent advances in antibody engineering have produced various artificially engineered antibodies and chimeras. Many of these molecules are superior to the natural antibody in aspects such as stability, size, low production cost, higher affinity, or have additional functions such as bi-specificity.

The isolated heavy and light chain variable domains (VH and VL) of an antibody constitute a heterodimer known as the Fv fragment, which contains a single antigen binding pocket. Fv fragments may dissociate at low protein. . . association between VH and VL did not depend on antigen specificity, and some variable domains associated better with a counterpart from another antibody molecule.

Isolated Fv fragments are expected to have better properties for penetration of solid tumor tissue, lower antigenicity, and improved pharmacokinetics. To prevent dissociation of the VH and VL, a single chain variable region (scFv) can be constructed in which the two variable domains are part of the same polypeptide chain, interconnected by a peptide linker (Tsumoto et al.). A comparison of strategies to stabilize immunoglobulin Fv fragments has been described by Glockshuber et al.

Various other constructs of antibody molecules have been prepared. Monoclonal antibodies of a non-human species can be humanized by placing the three antigen-binding CDR regions of each VH and VL of the specific antibody into the framework of human VH and VL- See, for example, EP 0329400.

Constructs have also been prepared in which antibody binding sites are part of a molecular

chimera. Maeda et al. proposed preparing a chimeric molecule in which an antibody binding monodomain was bioengineered onto *Vargula luciferase*. Ueda et al. (1992) constructed artificial chimeric cell-surface receptors, combining murine IgM with the cytoplasmic. . . constitutive and independent of antigen binding. With IgM lacking the CH<sub>2</sub> domain, autophosphorylation increased with increasing concentrations of hapten-  
- 2 -  
BSA conjugate. Monovalent hapten could not induce phosphorylation, but inhibited stimulation by the conjugate.

#### SUMMARY OF THE INVENTION

The fusion polypeptides of this invention contain a variable region sequence linked to an effector sequence. The polypeptides do not form stable complexes in solution, except in the presence of an antigen for which. . .

with each other in the presence of an antigen, consisting of a first fusion polypeptide comprising a first variable domain sequence linked to a first effector sequence, and a second fusion polypeptide comprising a second variable domain sequence

linked to a second effector sequence, wherein complexing between the first and second variable domain sequences in a solution is stabilized if. . .

each other in a solution containing the antigen; c) preparing a first fusion polypeptide in which the first variable domain sequence is linked to the first effector sequence, and a second fusion polypeptide in which the second variable domain sequence is linked to a second effector sequence; and d) confirming that 1 0 the first fusion polypeptide forms a complex with the second. . .

the combined variable region is specific for the model antigen hen egg lysozyme, and the effector sequences are monomer subunits of mitochondrial malate dehydrogenase.

FIG. 7 is a half-tone reproduction of a gel showing the size of the cloned encoding region for mitochondrial malate dehydrogenase.

0 a covalent linkage between the variable domain sequence and the effector sequence, which can be a peptide bond, a polypeptide linker sequence, or any other type of chemical structure covalently connecting the variable domain and the effector in a manner that permits the. . .

which is in the complexed configuration. The two solid lines show VH and VL domains (left and right) of a monoclonal antibody specific for the antigen hen egg lysozyme. In the presence of the antigen, the domains associate along an interface of opposing P-pleated. . .

Cross-linking by S.S. Wong, CRC  
Press, 1993.

with the specificity for a particular antigen is standard practice in the art. General techniques used in raising, purifying and modifying antibodies, and the design and execution of immunoassays, are found in *Handbook of Experimental Immunology* (D.M.

Freund's complete adjuvant for the first administration, and Freund's incomplete adjuvant for booster doses. The most common way to produce monoclonal antibodies is to immortalize and clone a splenocyte or other antibody-producing cell recovered from an animal that has been immunized. The clone is immortalized by a procedure such as fusion with a. . .

The treated cells are cloned and cultured, and clones are selected that produce antibody of the desired specificity. Specificity testing is performed on clone supernatants usually by immunoassay.

Other methods for obtaining specific variable regions from antibodies or T cells involve contacting a library of immunocompetent cells or viral particles with the target antigen, and growing out positively selected. . .

interacting variable regions. The most usual configuration of the fusion peptides is for the C-terminus of each variable region to be linked to the N-terminus of each effector, although other configurations are possible. It is also possible to trim a few residues from the. . .

The opposite approach - that is, adding a linker sequence between the variable sequence and the effector sequence on one or both chains - becomes increasingly more difficult with increasing length of the linker. Precedents for conformational shifts through a connector between neighboring domains certainly exists, however, most notably represented by the immunoglobulins themselves.

Where a linker is necessary, it is appropriate to begin with candidates that form a rigid bridge, such as a sequence predicted to form. . .

expressing a recombinant polynucleotide encoding it, either by PCR-type amplification or using a suitable expression vector, but polypeptide synthesis or conjugation of separate polypeptides using a cross-linking agent can also be used. The fusion proteins of this invention are designed to be freely soluble in solution, and are. . .

When adapted for use as biopharmaceuticals for human therapy, the variable region sequences, the effector sequences, and the linker sequences (if used) will typically be chosen to resemble human sequences as much as possible, to avoid immunogenicity. The specificity of. . .

converted into a prodrug according to the strategy outlined in USSN 60/[pending; attorney

docket 33746-3001 1.00]. The strategy involves using a cross-linking agent to form the prodrug into an inactive loop configuration. The loop contains either a protease recognition sequence in the amino acid sequence, or else an enzyme cleavable group within the cross-linker. Examples of 0 enzyme cleavable cross-linkers are outlined in USSN 08/883,632, and include those that are cleavable by glycosidase, phosphatase, amidase or esterase. The combined effector sequences. . . of the polypeptide pair mediating the prodrug activation would have the corresponding catabolic activity for either the peptide recognition sequence or the cross-linker

. . .  
and simplified using the polypeptide pairs of this invention. In one example, a plastic surface is coated with an antigen-specific capture antibody, the surface is contacted with the sample, and then the surface is contacted with the polypeptide pair. Presence of antigen in. . .

. . .  
Antigen-dependent association of V, and H  
This example describes binding experiments conducted using variable region sequences from anti-hen egg lysozyme (anti-HEL) monoclonal antibody with the designation HyHEL. The Fv fragment was previously known to form a trimolecular complex of 39 kDa in size, as. . .

. . .  
lysine residue (Lys 47) located at the VH. interface mutated to threonine, was made to exclude possible fragment association. The monoclonal antibody (Mab) with this mutation (VLK49T), which is analogous to HyHEL-8 VL, retains antigen binding affinity (Lavoie et al.). The mutant VL. . .

DETD. . . acid sequence encoding polypeptide or protein can be prepared using well known methods. The expression vectors include a DNA sequence operably linked to suitable transcriptional or translational regulatory nucleotide sequences, such as those derived from a mammalian, microbial, viral, or insect gene. . . enhancers, an mRNA ri-

bosomal binding site, and appropriate sequences which control transcription and translation initiation and termination. Nucleotide sequences are operably linked when the regulatory sequence functionally relates to the DNA sequence encoding the polypeptide or protein of interest.

For example, a promoter nucleotide sequence is operably linked to a DNA sequence encoding the protein or polypeptide of interest if the promoter nucleotide sequence controls the transcription of the. . .

. . . or a sense oligonucleotide, based upon a cDNA sequence for a given protein is described in, for example, Stein and Cohen, Cancer Res. 48:2659, 1988 and van der Krol et al., BioTechniques 6:958, 1988.

. . . of the polypeptides or proteins of the invention. Antisense or sense oligonucleotides further comprise oligonucleotides having modified sugar-phosphodiester backbones (or other sugar linkages, such as those described in WO91/06629) and wherein such sugar linkages are resistant to endogenous nucleases. Such oligonucleotides with resistant sugar linkages are stable in vivo (i. e., capable of resisting enzymatic degradation) but retain sequence specificity to be able to bind to target nucleotide sequences. Other examples of sense or antisense oligonucleotides include those olicronucleotides which are covalently linked to organic moieties, such as those described in W'0 90/10448, and other moieties that increases affinity of the olicTonucleotide for. . .

. . . Sense or antisense oligonucleotides also may be introduced into a cell containing the target nucleotide sequence by formation of a conjugate with a ligand binding molecule, as described in Alternatively, a sense or an antisense oligonucleotide may be introduced into a. . .

. . . can be treated in accordance with the invention include Creutzfeld-jacob's disease, Alzheimer's disease, Hunting-ton's disease, Ataxia type- 1, cystic fibrosis and cancer. The therapeutically effective dose is preferably delivered with a pharmaceutically acceptable carrier. More preferably, the pharmaceutically acceptable carrier is capable. . .

. . . relationship was investigated by altering the cellular levels of chaperones individually or in combination and analyzing chaperone-substrate interactions by co-immunoprecipitation with chaperone-specific antibodies.

. . . proteins that frequently occurs upon overproduction in bacteria. Furthermore, it was observed that aggregates of thermally denatured proteins (e.g., Malate Dehydrogenase, MDH) show increased staining with Congo red, a widely used marker stain indicative for amyloid fibers.

. . . was conducted to analyze the ability of various chaperones to

disaggregate  
I  
and refold aggregates of thermosensitive test proteins (including Malate Dehydrogenase (MDH)  
Z)  
and firef[v luc'ferase). Qualitatively similar results were obtained for all proteins tested, and the results for MDH are summarized in Figure 6 and Table 3, and described in more detail below.

Incubation of MDH at 47°C caused inactivation and formation of large aggregates, as judged by loss of its enzymatic activity, an increase in light. . . of aggregates. This is depicted in Figure 6A which shows the time-dependent inactivation and aggregation (increased turbidity at 550 nm) of mitochondrial

MDH (720 nM) at 47°C without chaperones and in the presence of DTT (10 mM). As shown in Table 3 and Figure 6A, neither ClpB nor the DnaK system alone, with or without ATP, was active in disaggregation and refolding of MDH. In contrast, as shown in Table 3 and Figure 6B (which shows the time-dependent disaggregation and reactivation at 25°C of MDH that had been aggregated by heat treatment as described above but supplemented with ClpB, DnaK, DnaJ and GrpE at concentrations of. . . of, ClpB and the DnaK system allowed complete solubilization within 30 min. and almost complete reactivation of up to 3 pM MDH within 3-4 hours.

100 24.5 12.2 Synechocystis#2  
0.8 E. coli  
00 H. pylori  
Example I 1: ClpS is established as a co-chaperone of ClpA Malate dehydrogenase (MDH) (0.9 μM) was aggregated, in the absence of chaperones, by incubation at 47°C for 30 minutes. With reference to Figure 14, following aggregation, MDH activity was monitored in the absence of chaperones (filled triangle), in the presence of 0.5 μM ClpS

(filled diamond), 0.5 ]M CIpA. . . 0.5 ]tM CIpS (filled circle). As indicated in Figure 14, in the absence of chaperones or the presence of CIpS alone, MDH did not regain significant activity. In the presence of CIpA alone, up to 30% MDH activity was obtained after 300 minutes. When CIpA is supplemented with ClpS, both the rate and the yield of MDH activity was enhanced more than two-fold. Thus, CIpS is established as a potent co-chaperone of CIpA.

CLMEN. . . The method of claim 25 wherein the disease is Creutzfeld-Jacob's disease, Alzheimer's disease, Huntington's disease, Ataxia type- 1, cystic fibrosis or cancer.
